

Painted fruit for Fruit Slice (ChatGPT prompt)

The game normally draws its 19 fruit itself. If you put a sprite sheet at `src/game/art/fruits.png` it draws those instead (nothing else changes: cutting still uses the invisible outline of each fruit, which is why the guide sheet shows those outlines).

Sharp version: 5 small pictures instead of 1 big sheet (recommended)

ChatGPT makes pictures of roughly 1024-1536 px. On one sheet of 19 fruit, each fruit gets only ~230 px, but the game shows a fruit up to ~420 px wide, so it looks soft. With **4 fruit per picture** each one gets ~450 px, which is sharp.

1. `node scripts/fruit-art.mjs guide batches` writes `art/batch-1.png` ... `batch-5.png` (2 x 2 fruit each, 1024 x 1024; already generated in this folder).
2. For each batch, one at a time, in one ChatGPT conversation: attach `art/batch-N.png` and send the prompt below with the fruit list of that batch filled in:

Batch	Fruit
1	1 orange, 2 apple (red), 3 watermelon (green stripes), 4 lemon (soft mustard yellow, NOT bright or neon)
2	5 pear, 6 banana, 7 kiwi (brown fuzzy skin), 8 dragonfruit (pink skin, green-tipped scales)
3	9 pineapple, 10 mango, 11 starfruit (yellow-green, five ridges), 12 pomegranate
4	13 passionfruit (a LIGHT, saturated violet - it must stand out on a dark purple background), 14 avocado (dark green, bumpy), 15 papaya, 16 lychee (rough pink-red skin)
5	17 coconut (brown, hairy, three dark spots), 18 strawberry (tiny seeds), 19 persimmon (orange) - the 4th cell stays empty magenta

3. From batch 2 on, also attach your **first result** and add: *"Match the style of the first result exactly: same outline thickness, shading, highlight and colour saturation."*
4. Ask for the **largest size** it can make (e.g. "1024 x 1024 or larger") and save each result as a PNG.
5. Convert all five, in order:

```
node scripts/fruit-art.mjs prepare art/b1.png art/b2.png art/b3.png art/b4.png art/b5.png
```

The converter reports every fruit as `found WxHpx -> wxhpx`; if it says **(enlarged ...: soft)** that fruit was too small in your picture, so regenerate that batch. You can also pass the one big sheet (it just gives a softer result), and `--cell 384` makes a smaller file (the default 512 is 2560 x 2048 and ~3 MB).

Prompt for one batch

I am attaching a layout image for a mobile game: a 2 x 2 grid. Each cell has a grey silhouette on a magenta background and a small label in its top-left corner naming the fruit.

Create a new image with EXACTLY the same layout (same size, same 2 x 2 grid), where each grey silhouette is replaced by a painted illustration of the fruit named in its label.

Style: polished casual mobile game art, like Fruit Ninja or a modern match-3. Clean, bold, slightly glossy cartoon rendering, soft cel shading with one simple highlight, a darker outline around the whole fruit in a deeper shade of its own colour, rich saturated colours. Each fruit is WHOLE and uncut, seen from the side or slightly from above, lit from the top left. Highly detailed, crisp, sharp edges, high resolution.

Hard rules:

- The fruit must fill its grey silhouette: same shape, same size, same position. Do not make it smaller or larger, and do not rotate it.
- Nothing may stick out of the silhouette. Stems, leaves and crowns must be painted INSIDE the silhouette on the fruit, not poking out of it.
- The background stays flat pure magenta (#FF00FF): no shadows, glow, gradient, texture or ground. Do not use magenta or pink-magenta on the fruit itself. Hard clean edges, no pink halo.
- No text, no labels, no numbers, no borders, no grid lines, no frame. An empty cell stays completely magenta.
- No extra objects (no knives, loose leaves, bubbles or splashes).

Fruit in this image (reading order, left to right, top to bottom): <PASTE THE ROW OF THE TABLE FOR THIS BATCH>

Quick version: one sheet (softer)

Generate the one sheet

1. Open ChatGPT (image generation on).
2. Attach `art/fruit-guide.png` (5 x 4 grid: each cell has a grey outline, the fruit's name in the top-left corner, and a magenta background).
3. Paste the prompt below, then send.

The prompt

I am attaching a layout sheet for a mobile game. It is a grid of 5 columns x 4 rows (19 used cells, the last one is empty). Each cell contains a grey silhouette on a magenta background, and a small label in the top-left corner naming the fruit (1. ORANGE ... 19. PERSIMMON).

Create a new image with EXACTLY the same layout (same 5 x 4 grid, same size and proportions, same order), where each grey silhouette is replaced by a painted illustration of the fruit named in its label.

Style: polished casual mobile game art, like Fruit Ninja or a modern match-3. Clean, bold, slightly glossy cartoon rendering, soft cel shading with one simple highlight, a darker outline around the whole fruit in a deeper shade of its own colour, rich saturated colours. Every fruit is shown WHOLE and uncut, seen from the side or slightly from above, lit from the top left. All 19 fruit must look like one family: same line weight, same shading, same level of detail.

Hard rules:

- The fruit must fill its grey silhouette: same shape, same size, same position. Do not make it smaller or larger, and do not rotate it.
- Nothing may stick out of the silhouette. Stems, leaves and crowns (apple stem, pineapple crown, strawberry leaves, dragonfruit scales...) must be painted INSIDE the silhouette on the fruit, not poking out of it.
- The background of every cell stays flat pure magenta (#FF00FF), with no shadows, glow, gradient, texture or ground. Do not use magenta or pink-magenta anywhere on the fruit itself.
- No text, no labels, no numbers, no borders, no grid lines, no frame. Leave the 20th cell completely magenta.
- Do not add any extra objects (no knives, no leaves lying around, no bubbles, no splashes).
- Keep the fruits in the exact cell order shown by the labels.

Fruit to paint (in order): 1 orange, 2 apple (red), 3 watermelon (green stripes), 4 lemon (a soft mustard yellow, not bright or neon), 5 pear, 6 banana, 7 kiwi (brown fuzzy skin), 8 dragonfruit (pink skin with green-tipped scales), 9 pineapple, 10 mango, 11 starfruit (carambola, yellow-green, five ridges), 12 pomegranate, 13 passionfruit (purple), 14 avocado (dark green, bumpy skin), 15 papaya, 16 lychee (rough pink-red skin), 17 coconut (brown, hairy, three dark spots), 18 strawberry (with tiny seeds), 19 persimmon (orange).

If the result is not good

- **Cells drift or the grid is off:** the converter re-centres and rescales every fruit inside its own cell, so small drift is fine. If whole fruit are missing or merged, ask for one row at a time: "*Same style and rules. Redo only row 2 (6. BANANA to 10. MANGO) as a 5 x 1 strip, with each fruit filling its grey silhouette on magenta.*", then paste the rows together (any image editor) or run the converter on a sheet you assembled.

- **Fruit does not fill the silhouette:** say "Each fruit must touch all the edges of its grey silhouette: stretch it to fill it". The converter fits by the fruit's visible bounding box, so a fruit that is too small just gets scaled up.
- **Pink/magenta fringe around fruit:** ask for "hard clean edges, no anti-aliased pink halo, flat #FF00FF background".
- **Style differs between fruits:** regenerate and say which numbers to match to which.

Put the sheet in the game

Save ChatGPT's picture somewhere (for example `art/chatgpt-sheet.png`), then:

```
node scripts/fruit-art.mjs prepare art/chatgpt-sheet.png
```

(Set `CHROMIUM_PATH` to Chrome's `chrome.exe` if the script cannot find a browser.) It removes the magenta, finds each fruit in its cell, fits it onto the game's outline, prints what it found per fruit (`NOTHING FOUND` means that cell was empty), and writes `src/game/art/fruits.png`.

Check it with `npm run dev` and open `http://localhost:5173/?gallery=1` to see all 19, then play. The game needs `src/game/art/fruits.png`; without it fruit show as plain flat silhouettes.

How it works (so you can change it)

- `scripts/fruit-art.mjs` `guide` regenerates `art/fruit-guide.png` from the game's real fruit outlines (do this if you change a shape in `src/game/sim/fruit.ts`).
- The sheet in the game is 5 columns x 4 rows of square cells (default 512 px, so 2560 x 2048), in the order of `FRUIT_KINDS`. Each fruit is centred on its cell and its outline reaches 7/16 of the cell size from the centre.
- `src/game/view/fruitSprites.ts` loads it and draws each fruit as a sprite scaled to the fruit's radius. Cut halves are the same sprite hidden by a half-plane mask.
- Adding a 20th fruit: add the kind in `sim/fruit.ts` (it takes the last free cell), regenerate the guide, repaint.
